129	174	138

成绩单编号：152145108004527

given conductivity, the deciduous tree species exhibited stronger vessel wall reinforcement (safety) than the evergreen tree species, which might be due to the fact that evergreen trees species had more axial parenchyma. Hence, this study revealed the specificity of xylem anatomy in karst tree species. Water and resource storage in xylem parenchyma are vital to karst trees (evergreens in particular) for their adaptation to the water-limiting environment.

Key words vessel, parenchyma; fibers, vessel wall reinforcement coefficient; theoretical hydraulic conductivity; trade-off

我国西南喀斯特是世界喀斯特连片分布面积最大的区域, 总面积超过55万 km^2 , 主要集中在广西、贵州和云南等省区(宋同清, 2015)。其中, 广西喀斯特分布面积达9.7万 km^2 , 喀斯特地貌富有特色(蒋忠诚等, 2007)。由于广西地处云贵高原的东南缘、南临北部湾, 受热带亚热带季风气候影响, 高温多雨, 岩溶作用强烈, 喀斯特地貌以峰丛洼地、峰丛谷地为主(袁道先, 1992)。与非喀斯特地区相比, 喀斯特环境具有岩石(碳酸盐岩)裸露程度高、土壤稀薄、水分下渗快等特点(袁道先, 1992; 陈洪松等, 2013)。喀斯特生态系统较为脆弱, 受长期人类活动影响, 植被退化严重; 其中广西喀斯特石漠化面积达2.37万 km^2 , 生态环境问题突出(胡宝清, 2014)。广西喀斯特地区的植物多样性高(宋同清, 2015)。为喀斯特石漠化地区的植被重建提供了丰富的“乡土恢复工具树种库”, 因此亟需了解喀斯特植物的生理生态适应性(曹坤芳等, 2014)。

由于喀斯特生地的水分有效性低, 喀斯特森林植物具有明显的旱生性特点(彭晚霞等, 2008)。喀斯特植物的生理生态适应性, 尤其是水分生理研究受到广泛关注(Wang *et al.*, 2018; Chen *et al.*, 2019)。研究表明喀斯特树种可以通过较强的生理调整能力适应水分亏缺(Cao *et al.*, 2020), 或通过发达的根系扩大水分来源(Geekiyana *et al.*, 2019)。前期基于中亚热带喀斯特地区的喀斯特木本植物脆弱性曲线分析发现喀斯特树种抗栓塞能力并不高于同区域的非喀斯特森林树种(Fan *et al.*, 2011; 谭凤森等, 2019)。另外, 研究发现植物薄壁细胞比例高的其非结构性碳水化合物含量高(Plavcová *et al.*, 2016; Pratt & Jacobsen, 2017), 可能高的薄壁细胞比例在抗旱性方面发挥作用(Tomásella *et al.*, 2019)。因此研究喀斯特树木的木质部结构特征有助于理解喀斯特植物的干旱适应性。

木本植物木质部主要由导管(或管胞)、纤维和薄壁细胞组成, 各自执行不同的功能: 导管(或管胞)负责水分和无机离子的运输; 薄壁组织负责水和碳水化合物化合物的储存; 纤维主要负责机械支持(Hacke & Sperry, 2001; Plavcová & Jansen, 2015; Morris *et al.*, 2016b)。木质部不同组织相互联系, 形成有机整体, 为植物体正常有序的生理过程提供保障(周朝彬等, 2016)。由于木质部空间(横截面积)限制, 导管组织、纤维组织、薄壁细胞组织的比例存在权衡关系, 即分配给某一组织较多的空间, 会减少其他组织的可用空间(Pratt & Jacobsen, 2017)。木质部组织分配的最优化有助于木质部发挥其最大的功能(Carlquist, 2018), 体现了其对生存环境的适应(Godfrey *et al.*, 2020)。

广西木论喀斯特位于西南喀斯特的核心区域, 保存有连片面积最大、原生性较强的喀斯特森林(刘璐等, 2012)。顶极群落类型为中亚热带常绿落叶阔叶混交林; 与同区域的非喀斯特森林相比, 落叶树种的比例较高。落叶与常绿植物的生理生态特征具有显著差异, 基于木质部结构方面的研究表明落叶植物具有较低的木材密度、较小的导管密度以及较大的导管直径(Choat *et al.*, 2005)。本研究选取木论喀斯特常绿落叶阔叶混交林21种典型树种(包括11种常绿树种和10种落叶树种), 测定枝条木质部解剖结构并计算相关水力功能性状。主要研究以下3个问题: (1)与全球数据相比, 喀斯特树种木质部解剖结构特征有何特殊性? (2)喀斯特树种木质部各组分之间是否具有显著的权衡关系? (3)喀斯特落叶与常绿树种的木质部结构和水力特征有何差异?

摘要 树木木质部主要由导管、纤维和薄壁组织组成, 分别具有运输、支撑和贮存的生理功能。由于木质部空间限制, 一种组织比例的增加会导致其他组织比例的降低, 因而可能表现出权衡关系。分析木质部组织比例和权衡关系有助于了解植物的生理生态适应性。本研究选择中亚热带喀斯特常绿落叶阔叶混交林21种典型树种(10种落叶树种, 11种常绿树种), 测定枝条木质部各组织比例, 计算水力相关指标并分析性状之间的相关性。结果表明: (1)与全球木质部解剖数据对比分析, 喀斯特树种木质部趋向具有较高比例的薄壁组织; (2)喀斯特树种导管组织比例与薄壁和纤维组织比例之间没有显著的相关性, 但是薄壁和纤维组织比例之间有显著的权衡关系; (3)常绿和落叶树种的木质部水力运输安全性(导管壁加固系数)和效率性(理论导水率)均具有显著的权衡关系, 但是这两个类群线性回归的截距存在显著差异。即在相同的理论导水率条件下, 落叶树种比常绿树种具有较高的导管壁加固系数(安全性), 可能与常绿树种具有更多的轴向薄壁组织有关。喀斯特树种木质部解剖特征表明薄壁组织的贮存功能对喀斯特树种(尤其是常绿树种)的干旱适应具有重要作用。

Abstract

Aims Vessel, fibers, and parenchyma are the main components of tree xylem. They are responsible for water transport, mechanical support, and water and nutrients storage. Given the limited xylem space, consistent investment in one type of tissue would constrain the space available for other types of tissue, thus resulting in a possible trade-off among different tissues in their fractions. Analysis of the fractions of tissue types in xylem and the trade-off would contribute to better understanding of the eco-physiological adaptation of plants.

Methods We selected 21 characteristic tree species (10 deciduous and 11 evergreen) from a mixed evergreen and deciduous broad-leaved forest located in the mid-subtropical karst region, and measured their xylem tissue fractions. In addition, we calculated the hydraulic-related structural traits in xylems and examined the correlations among various traits.

Important findings Compared to the global average values of xylem tissue fractions, the karst tree species tended to have a higher proportion of parenchyma. The fraction of vessel lumen was not correlated with fiber and parenchyma fractions across the tree species investigated. Instead, a significant trade-off was observed between fractions of fiber and parenchyma. A trade-off between the hydraulic efficiency (i.e. theoretical hydraulic conductivity) and safety (vessel wall reinforcement) was observed across both the deciduous and the evergreen tree species. The two contrasting group of karst trees differed significantly in the intercepts of the lines for trade-offs. For

论国家级自然保护区的永久性监测样地(25.15° N, 108.04° E), 海拔420 m。受季风气候影响, 该样地年平均气温19.2 °C, 年降水量1529.2 mm; 雨季为4-8月, 降水量占全年的73.7% (刘璐等, 2012)。森林群落类型为中亚热带喀斯特常绿落叶阔叶混交林, 样地面积为1 hm² (100 m × 100 m), 东南向, 处于喀斯特峰丛洼地中上坡, 平均坡度约27°, 岩石裸露率80%-90% (郑颖晋, 1999)。样地共有物种44科73属95种; 重要值靠前的树种为青檀(*Pteroceltis tatarinowii*)、广西密花树(*Myrsine kwangsiensis*)、千里香(*Murraya paniculata*)和菜豆树(*Radermachera sinica*)等。土壤以石灰土为主, 有机碳含量为15-24 g·kg⁻¹ (刘淑娟等, 2010; 宋同清, 2015)。

1.2 实验材料

取样时间为2019年8月, 选取样地中21种典型的喀斯特木本植物, 隶属于14科21属, 其中落叶10种, 常绿11种(表1)。根据树种的平均树高与胸径, 每种选取5株健康成熟个体, 从每个个体上剪取2段冠层阳生枝条, 长度5 cm, 直径为7-10 mm。

1.3 测定方法

将采回的新鲜枝条放入贴好标签的离心管中, 用FAA溶液固定一周后, 将样品固定在滑走切片机(Leica SM2010R, Leica, Nusslock, Germany)的凹槽进行横切, 切片厚度为25 μm, 用乙酸乙酯溶解泡沫(聚苯乙烯)的混合液涂抹样品切面防止切片变形(Barbosa *et al.*, 2010)。用鸡蛋清和甘油的混合液把切片粘在载玻片上, 再用番红溶液和阿利新蓝溶液染色, 依次经过浓度为40%、70%、90%、100%的酒精脱水后用加拿大树胶固定。利用光学显微镜(Leica DM 3000, Leica, Wetzlar, Germany)观察并对木质部横切面(边材)进行拍照。每个个体制作2个切片, 每个切片分别在10、20、40倍镜下随机拍摄4个视野。

利用ImageJ 1.52软件(www.imagej.nih.gov, USA; Rueden *et al.*, 2016)对染色后的切片图(图1)进行分析处理, 得出以下指标: (1)导管密度(*V_d*), 即单位视野内的导管数量(Perez-Harguindeguy *et al.*, 2013); (2)导管比例(*V_s*)、环管胞比例(*T_r*)、导管壁比例、轴向薄壁组织比例(*AP_f*)、射线组织比例(*RP_f*)以及纤维组织比例(*FB_f*), 其中薄壁组织在次生木质部中是

3 讨论

3.1 喀斯特树种木质部具有较小的导管水力直径和较大比例的轴向薄壁组织

与全球木本植物木质部解剖结构数据相比, 喀斯特树木的木质部趋于具有较高比例的轴向薄壁组

织(图2)。已有研究表明薄壁组织具有贮存水分、储存和转运碳水化合物的功能(Plavcová & Jansen, 2015; Morris *et al.*, 2016b), 在维持植物水分平衡(Meinzer *et al.*, 2009)和修复导管栓塞过程中发挥重要作用(Zwieniecki & Holbrook, 2009; Tomasella *et al.*, 2019)。木质部中高的薄壁组织比例具有高的水容(Secchi *et al.*, 2017; Santiago *et al.*, 2018), 当土壤有效水分供给不足时, 高的水容可以缓解土壤与叶片的水势差, 从而维持叶片的气体交换(McCulloh *et al.*, 2019; Siddiq *et al.*, 2019)。最近对温带带灰岩山地的19种阔叶树种的研究发现, 木质部薄壁细胞比例与抗栓塞能力具有显著的负相关关系(Chen *et al.*, 2020)。以上研究结果证明了薄壁细胞的贮存能力对喀斯特树种的干旱适应具有重要作用(谭凤森等, 2019), 也解释了中亚热带喀斯特树种较低的抗栓塞能力(Fan *et al.*, 2011)。

本研究中喀斯特21种树种木质部导管水力直径(平均值为44.76 μm)显著地低于全球木本植物的平均值(94.43 μm ; Morris *et al.*, 2018)。在西南热带喀斯特森林的研究也发现喀斯特树种的导管直径要显著地低于临近的沟谷雨林树种(Zhu *et al.*, 2017), 体现了对喀斯特旱生生境的水力适应(Hacke *et al.*, 2017)。与其他树种不同, 青冈和铁榄的木质部导管周围具有直径较小的环管管胞(图2), 而且它们主要分布在喀斯特峰从洼地上坡更为干旱的生境。同样,

图1 菜豆树木质部染色切片(A)和经过人工辨别和绘制后的木质部组织结构分布图(B)。绿色, 导管管腔; 黄色, 导管壁; 红色, 射线细胞; 蓝色, 轴向薄壁细胞; 紫色, 纤维细胞。

Fig. 1 A stained xylem cross-section image of *Radermachera sinica* (A), and the same image in which different xylem tissues were manually coded with different colors (B). Green, vessel lumen; Yellow, vessel wall; Red, ray parenchyma; Blue, axial parenchyma; Purple, fibers.

(1) 导管水力直径(Dh)的计算公式参照Tyree和Zimmermann (2002):

$$Dh = \sqrt[3]{\frac{\sum_{i=1}^n b_i^4}{n}} \quad (1)$$

式中, b_i 表示单个导管长短轴直径的平均值。

(2) 理论导水率(Kt), 反映木质部水分运输的效率性。计算公式参照Tyree和Zimmermann (2002):

$$Kt = \frac{\rho\pi}{128\eta} \times Vd \times Dh^4 \quad (2)$$

式中, Vd 表示导管密度, Dh 表示导管水力直径, ρ 表示20℃下水的密度998.2 kg·m⁻³, η 表示20℃下水的黏度1.002 × 10⁻⁴ MPa·s。

1.4 数据分析

全球木本植物木质部组织比例数据从TRY Database (Kattge *et al.*, 2020) 下载, 利用R 3.5.0 软件进行统计分析。用ggtern软件(Hamilton & Ferry, 2018) 绘制本论和全球的木质部组织比例三角坐标图; 用stats R 软件中的t.test 公式分析常绿与落叶树种木质部解剖结构和水力特征的差异显著性; 用factoextra 软件的PCA 公式做主成分分析。利用smatr R 软件中的sma 公式通过简化主轴回归分析(Warton *et al.*, 2012) 来分析本论和全球树种木质部各组织比例之间的相关性、理论导水率与导管壁加固系数的相关性, 以及落叶与常绿树种直线回归斜率和截距的差异性。所有图用R-package 软件的base 绘制。

2 结果

2.1 喀斯特树种木质部解剖特征与全球木本植物数据的比较

本研究测定的喀斯特树种木质部轴向薄壁组织比例的种间变异较大(变异系数为54.6%), 最低值为2.6% (大叶紫珠(*Callicarpa macrophylla*)), 最高值为31.0% (青冈(*Cyclobalanopsis glauca*))。射线组织比例的变异系数是29.1%, 最小值是8.7% (千里香), 最大值是29.6% (灰岩棒柄花(*Cleidion bracteosum*))。导管组织比例的种间差异相对较小, 变异系数为26.2% (图2; 附录I)。铁楸(*Sinosideroxylon pedunculatum*)和青冈的导管周围有环管胞, 其环管胞面积分别占木质部横截面积的12.1%和12.6% (图2; 附录II)。与全球木本植物木质部组织比例数据对比分析, 本研究21种喀斯特树种木质部纤维组织和导管组织比例分别为全球数据平均值的87%和90% (图2), 但是这些喀斯特树种的木质部趋于具有较高比例的轴向薄壁组织, 其平均值是全球数据平均值的4.3倍(图2, 图3A)。

2.2 喀斯特树种木质部各组分之间的权衡关系

基于全球805种木本植物木质部解剖结构数据, 各组分比例之间存在显著的权衡关系。喀斯特树种木质部各组织比例的相关关系与全球数据的分析结果不完全一致: 喀斯特树种的纤维组织比例与薄壁组织比例存在显著的权衡关系, 但是导管组织比例与纤维组织比例和薄壁组织比例均不存在显著的相关关系(图3B)。

2.3 喀斯特常绿与落叶树种木质部水力特征的差异

主成分分析结果表明第1轴解释总变异的39%, 与木质部导管的管径(Dh 、 Vd)相关; 第2轴解释总变异的22%, 与木质部的贮存(TPF)和水分传导率(Kt)相关(图4A)。常绿和落叶树种在第2轴可以显著区分为两个类群, 常绿树种具有较多的轴向薄壁细胞和较低的理论导水率($p < 0.001$; 图4B; 附录I)。不论常绿树种还是落叶树种, 理论导水率和导管壁加固系数之间均呈显著的负相关关系; 但是这两个植物类群的直线回归方程的截距具有显著差异($p = 0.002$), 即在理论导水率相同情况下, 落叶树种具有更高的导管壁加固系数(图5)。

在加利福尼亚南部干旱灌木林(Hacke, 2015)和海南红树林(邓传远等, 2015)也发现优势树种木质部存在环管胞。环管胞本身除了具有水分运输的功能外, 当植物面临水分胁迫时还能够连接被栓塞阻隔的导管, 从而保证了水分运输的安全性(Carlquist, 2001)。喀斯特树种的环管胞的生理作用值得进一步探讨。

3.2 喀斯特树种木质部各组分的权衡关系

与全球数据的分析结果不同, 喀斯特树种木质部导管组织比例与其他组织比例之间的相关性均不显著(图3)。这一结果与加利福尼亚干旱森林树种的研究结果(Pratt & Jacobsen, 2017)相似, 可能与这些木本植物具有相对稳定的导管组织比例有关。喀斯特树种木质部纤维组织比例与薄壁组织比例存在显著的权衡关系(图3)。这些树种的木质部倾向于具有较高的薄壁组织比例而不是纤维组织, 它们可能通过提高栓塞修复能力(而非抗栓塞能力)适应干旱(Pratt & Jacobsen, 2017; Janssen *et al.*, 2020; Aritsara *et al.*, 2021)。较低的纤维组织比例(支撑作用)也从木质部结构的角度解释了为什么中亚热带的喀斯特森林冠层高度要显著低于同区域的亚热带常绿阔叶林(平均林冠高度为28.90 m; Liu *et al.*, 2019)。

3.3 喀斯特落叶与常绿树种木质部解剖和水力特征的差异

本研究发现喀斯特落叶与常绿树种的导管水力直径和导管密度没有显著差异, 但是落叶树种的理论导水率是常绿树种的两倍(附录I)。根据Hagen-Poiseuille定理, 理论导水率与导管直径的4次方成正比, 导管直径的较小差异(喀斯特落叶树种比常绿树种的平均值高25%), 导致理论导水率的较大变化。本研究发现木质部水分运输效率性(理论导水率)与安全性(导管壁加固系数)之间存在权衡关系, 但是落叶与常绿树种具有显著差异: 若导管壁加固系数相同, 落叶树种具有较高的水分运输效率; 若导水率相同, 常绿树种反而具有较低的抗栓塞能力。这与以往研究发现同一森林中常绿植物比落叶植物具有更强的抗栓塞能力的结果相反(Chen *et al.*, 2009; Fu *et al.*, 2012), 原因可能在于本研究的喀斯特常绿树种具有丰富的轴向薄壁细胞(附录I), 并不依赖强的抗栓塞能力适应干旱。

通过长期的隔离降雨模拟试验, 结果发现干旱加剧会导致热带季节性森林中落叶植物成分显著增

加(Aguirre-Gutiérrez *et al.*, 2019)。在气候变化背景下, 我国亚热带地区呈现显著的干热化趋势(Qu & Huang, 2018; Yin *et al.*, 2018)。由于亚热带喀斯特森林对气候变化的响应较为敏感, 干旱程度的增加将会影响喀斯特森林群落的组成和物种多样性, 并进一步影响森林生态系统的结构和功能。基于喀斯特树种木质部解剖结构和水力特征的研究有助于了解它们对于旱的水力适应, 从而提高对树种动态变化的预测性。

4 结论

本研究揭示了中亚热带喀斯特森林树种木质部普遍具有较高比例的薄壁组织, 表明薄壁组织的贮存和修复能力对维持喀斯特树种木质部的水力安全至关重要。对喀斯特常绿和落叶树种木质部特征的比较结果表明, 落叶树种木质部倾向于提高水分运输效率, 而常绿树种则倾向于投资更多的薄壁组织用于调节水分平衡。结合喀斯特树种木质部功能性状与树种动态变化(生长和死亡)的研究有助于理解喀斯特森林对气候变化的响应。

(c) Xylem transversal section of *B. minus* to illustrate tissue fraction and (d) tissue fraction and arrangement analysis with the same scaling as panel (c). Vessel lumina are shown in white, vessel walls are in red, rays are in blue, axial parenchyma are in orange and fibers are in cyan.

(Rennolls 1978, Vallet and Perot 2016). Furthermore, 95% of the trees have a DBH of <25 cm. *Pteroceltis tatarinowii*, *Radermachera sinica* and *Chukrasia tabularis* are the most dominant species. The mean annual rainfall is 1529 mm, 73.7% of which falls between April and August. Further, the mean monthly temperature varies from 9.3 °C in January to 26.9 °C in July, with an annual average of 19.3 °C (China Meteorological Data Service Center, <https://data.cma.cn/en>).

We selected 21 co-occurring woody plant species from a 1-ha permanent plot (Table 1) and one particularly abundant species in the region's karst habitats (Lu et al. 2021). The importance value index (IVI) of each species was calculated by summing its relative frequency, density and basal area (Cottam and Curtis 1956), and the studied species were selected homogeneously along the IVI range. The 22 selected species differed in leaf habits; namely, 15 species are evergreen and seven are deciduous.

Growth rate and dynamics

An improvised apparatus made of stainless belts tightened with a spring was installed at 1.30 m height on 3–185 random trees per species (all with DBH greater than 5 cm) in July 2018 to measure tree growth increment. Growth increment was monitored annually for 3 years (2019, 2020 and 2021). The growth rate was quantified as the yearly average of DBH

increase across the 3 years as follows:

$$DGR_i = \frac{\sum_{t=0}^n (DBH_{t+1} - DBH_t)}{n} \quad (1)$$

With the observation of different growth rates of large and small trees during growth monitoring campaigns, size–growth scaling relationships were analyzed following Iida et al. (2014):

$$R_i = r_{1i} + r_{2i} \cdot \ln(D_{1i}) \quad (2)$$

$$\ln(D_{2i}) = \ln(D_{1i}) + R_i \cdot (t_1 - t_2) \quad (3)$$

where R_i is the relative growth rate of each species, and r_{1i} and r_{2i} are the model's intercept and slope, respectively. Thus, a positive r_{2i} suggests an increase in growth rate with increasing DBH; thus, r_{2i} quantifies 'growth acceleration.' D_{1i} and D_{2i} are the diameters of the tree i in consecutive years 1 (t_1) and 2 (t_2), respectively. The correlations between hydraulic traits and r_{2i} were analyzed only across species for which Eq. (2) was significant.

Hydraulic conductivity and embolism resistance

Samples from individuals growing near the inventory plot were collected in the early morning. For each of the 22 species, branches were collected from at least five individuals, except for

Karst forests are habitats in which access to soil water can be challenging for plants. Therefore, safe and efficient xylem water transport and large internal water storage may benefit tree growth. In this study, we selected 22 tree species from a primary subtropical karst forest in southern China and measured their xylem anatomical traits, saturated water content (SWC), hydraulic conductivity (K_s) and embolism resistance (P_{50}). Additionally, we monitored growth of diameter at breast height (DBH) in 440 individual trees of various sizes over three consecutive years. Our objective was to analyze the relationships between xylem structure, hydraulic efficiency, safety, water storage and growth of karst tree species. The results showed significant differences in structure but not in hydraulic traits between deciduous and evergreen species. Larger vessel diameter, paratracheal parenchyma and higher SWC were correlated with higher K_s . Embolism resistance was not correlated with the studied anatomical traits, and no tradeoff with K_s was observed. In small trees (5–15 cm DBH), diameter growth rate (DGR) was independent of hydraulic traits. In large trees (> 15 cm DBH), higher K_s and more negative P_{50} accounted for higher DGR. From lower to greater embolism resistance, the size–growth relationship shifted from growth deceleration to acceleration with increasing tree size in eight of the 22 species. Our study highlights the vital contributions of xylem hydraulic efficiency and safety to growth rate and dynamics in karst tree species; therefore, we strongly recommend their integration into trait-based forest dynamic models.

Keywords: embolism resistance, hydraulic efficiency, karst forest, tree growth, water storage, xylem anatomy, xylem parenchyma.

Introduction

Carbon and water cycles are strongly associated with evapotranspiration and primary production in plants. The rate of water transpiration from leaves is strongly and positively correlated with the leaf photosynthetic rate (Brodribb 2009, Scoffoni et al. 2016). However, water has to be channelled from the soil to the canopy via the xylem (Petit and Hampe 2006). Indeed, the links between stem xylem structure, hydraulics and tree growth have been demonstrated by numerous studies (Enquist et al. 1999, Tyree and Zimmermann 2002, Zhang and Cao 2009, Fan et al. 2012), and tradeoffs between fundamental functions,

such as xylem hydraulic conductivity (K_s), storage capacity and embolism resistance, have been frequently reported (Gleason et al. 2016, Pratt and Jacobsen 2016, Chen et al. 2020, Su-B. Zhang et al. 2022b). Therefore, these three xylem hydraulic traits must be balanced according to the growing environment's requirements to ensure a species' survival, growth and overall competitiveness (Lebrija-Trejos et al. 2010).

Xylem functional traits and strategies vary across species, phylogeny and habitats (Scholz et al. 2007, Feild and Wilson 2012, Jansen et al. 2020, Laughlin et al. 2020), and tree growth depends on the interaction between multiple functional

traits (Lebrija-Trejos et al. 2010, Rowland et al. 2021). For instance, large vessel diameter, low wood density (WD) and high K_s are often associated with rapid tree growth (Enquist et al. 1999, Fan et al. 2012, Eller et al. 2018). However, a 20-year rainfall exclusion experiment showed that water limitations may alter general trait–growth relationships (Rowland et al. 2021). Therefore, trees growing in a habitat under atypical conditions require special adaptation.

Karsts cover a large fraction of the southwestern region of China, and environmental conditions in karsts differ from those in any other habitat (Chen et al. 2010). Specifically, karsts are formed by carbonate deposits that have undergone millions of years of erosion leaving behind rocky skeletons covered with thin and isolated soil layers (Geekiyanaige et al. 2019). In these environments, the soil is typically poor in nutrients and water storage is limited despite sufficient precipitation, because most rainwater runs off or infiltrates through rock cavities (J. Zhang et al., 2022a). Nevertheless, trees growing in this habitat form a forest with a unique composition and structure (Nie et al. 2019). The differences in functional traits and floristic composition between karst and non-karst forests suggest strong environmental filtering in karst forests (Fu et al. 2019, Nie et al. 2019, Zhang et al. 2021). Therefore, peculiar trait–growth relationships are expected to occur in karst forests.

From a xylem hydraulic perspective, three hypotheses related to fast and sustained resource transport can tentatively explain how xylem hydraulic efficiency, safety and water storage, which are three major aspects of plant hydraulics, may promote tree growth in karst habitats. (i) High xylem hydraulic efficiency is hypothesized to promote fast resource transport, thereby supporting high photosynthetic rate (Brodribb 2009) and consequently, allowing rapid growth rate. (ii) High xylem hydraulic safety is hypothesized to sustain water transport even under low water availability (Li et al. 2009), thus, resulting in a high cumulative growth rate. (iii) Under low water availability, high-water storage is hypothesized to buffer the xylem tension to maintain the integrity of highly efficient but fragile conduits, thereby allowing transpiration extending photosynthetic active period during water stress (Chapotin et al. 2006, Scholz et al. 2007). Thus, high-water storage may also support high cumulative photosynthesis, and thus a high growth rate. If a tradeoff exists between hydraulic efficiency, safety and water storage in karst tree species as in species from other habitats (Pratt and Jacobsen 2016), then species combining high hydraulic efficiency, safety and storage, and synchronized correlations of high hydraulic efficiency, safety and storage with high growth rate, are less likely. A study on early angiosperms showed that xylem parenchyma may alter these tradeoffs (Aritsara et al. 2021). Therefore, these tradeoffs have to be tested before analyzing the contribution of these three hydraulic features to tree growth of karst species.

Owing to strong environmental filtering in karst habitats, the adaptation strategy adopted by tree species in these habitats may affect their growth. The occurrence of both deciduous and evergreen species in Chinese karst habitats (Du et al. 2017) suggests the coexistence of different growth strategies. Compared with evergreen species, deciduous species generally exhibit higher photosynthetic activity when resources are abundant; thus, they adopt a fast resource-acquisition strategy, which also coordinates with xylem structure and hydraulic functions (Choat et al. 2005, Qi et al. 2021). Deciduous species perform well in habitats with stronger seasonality (Givnish 2002). Thus, leaf habit potentially modifies the relationship between xylem hydraulic traits and tree growth in karst habitats.

Additionally, the metabolic theory of ecology proposes a general scaling between tree size and growth (Enquist et al. 1999, Muller-Landau et al. 2006). Understory trees have limited light resources and are exposed to low evaporative demand. Contrastingly, large trees have access to a relatively deeper water reservoir and a larger soil volume to uptake water; however, water has to be transported over a longer distance (Pelj and Harpe 2006). Large trees also have a large canopy and are constantly exposed to higher irradiations and stronger winds (Anten and Schieving 2010, Meinzer et al. 2011). Additionally, energy and biomass costs related to aging, reproduction and respiration increase as the tree grows (Spicer and Holbrook 2007, Meinzer et al. 2011). The constraints on growth and trait–growth relationships change accordingly. Therefore, the hydraulic basis of the scaling relationship between tree size and growth needs to be clarified.

This study aimed to identify the contribution of vessel and parenchyma structure to xylem hydraulic traits and, subsequently, tree growth in a subtropical karst forest. We hypothesized that the association of large vessels with paratracheal parenchyma alters the hydraulic tradeoffs, and improves the xylem hydraulic efficiency, safety and water storage of karst species. Our second hypothesis was that the coordinated improvement of these three aspects of xylem hydraulics promotes rapid tree growth and modulates growth–size scaling relationships in karst species.

Materials and methods

Study site and plant materials

This study was performed in the Mulun National Nature Reserve (25°5'9" N, 108°2'23" E, 420 m elevation; Figure 1), where relatively well-preserved subtropical evergreen–deciduous mixed forests grow in a karstic formation. Based on a 2018 survey, these forests contain 879 trees per hectare—with a diameter at breast height (DBH) larger than 5 cm. The total basal area is 125 m² per hectare, and the dominant height (the average height of the 100 largest trees) is 10.9 m

an elliptical disk with an elliptical central hole representing the pith.

During dehydration, deciduous species, such as *R. sinica*, were completely shed their leaves before the water potential reached P_{50} . Thus, their vulnerability curve was constructed as far beyond P_{50} as water potential and flow rate were accurately measured. The average K_{max} of branches with a water potential between -0.5 and 0 MPa was used to represent the species K_s . The other leafy branches were left on the ground to dry. Before subsequent measurements, they were covered with a plastic bag to equilibrate the water potential. Later, the percentage loss of conductivity (PLC) was calculated using Eqn. (5) as follows:

$$PLC = \frac{K_{max} - K_0}{K_{max}} \times 100 \quad (5)$$

The vulnerability curves were fitted to a double-parameter Weibull function using the *fitplc* R-package, which allows the estimation of the water potential at 50% loss of conductivity (P_{50}) for each species (Duursma and Choat 2017). P_{50} represents the xylem embolism resistance.

Wood density, saturated water content and xylem anatomy

Five 10-cm-long segments from five distinct individuals were cut from the segment used for K_s measurements. The segments were located ~ 1 m from the tip to avoid errors due to vessel tapering (Olson and Rosell 2013). Half of the segment was used for xylem anatomy measurements, and the other half for WD and saturated water content (SWC) measurements.

The portion dedicated to wood anatomy was stored in a formalin–alcohol–acetic acid fixation solution (10:50:5/distilled water 35; Ruzin 1999) and processed within 2 months. Before sectioning, a polystyrene and ethyl acetate solution was used to prevent tissue deformation (Barbosa et al. 2010). Subsequently, 25- μ m thick sections were cut using a sliding microtome (Leica SM2010 R, Nusslock, Germany). Sections were stained with safranin and Alcian blue and then mounted on Canadian balsam (Figure 1c). Images were captured using a light microscope (Leica DM 3000 LED; Wetzlar, Germany). Xylem tissues were manually identified in each image and delimited using a modified polyline tool in ImageJ (Figure 1d) and a drawing pad (BOSTO 16HDK, Guangdong, China). The diameter d_i of each vessel i was calculated from its area assuming a circular shape, and the mean hydraulically weighted diameter (Dh) of each individual was calculated as per Eq. (6) (Tyree and Zimmermann 2002):

$$Dh = \frac{1}{n} \sqrt{\sum_{i=1}^n d_i^4} \quad (6)$$

The relative area occupied by each tissue on the cross-section represented the tissue fraction. In addition, vessel connectivity with xylem tissue was analyzed following Aritsara et al. (2021).

Briefly, this analysis determined the relative length of the vessel perimeter in direct contact with other xylem tissues; that is, vessel–vessel connectivity, vessel–axial parenchyma connectivity (VAP), vessel–ray connectivity, vessel–fiber connectivity (VFc) and vessel–tracheid connectivity. The last parameter only applied to the two species with apparent vasicentric tracheids (identified from longitudinal sections).

The segment dedicated to WD and SWC measurements was debarked, and the pith was removed. The sample was immersed in distilled water for 24 h. Then, the saturated mass was weighted on a scale with 10^{-4} resolution (MT204T; Shanghai, China). The saturated volume (V_{sat}) was measured on the same instrument using the liquid displacement principle (Perez-Harguindeguy et al. 2013). The sample was oven-dried for >72 h at 70°C , and the dry mass (DM) was measured. WD is the ratio of DM to V_{sat} , and SWC is the saturated water weight relative to DM .

Statistical analysis

All statistical analyses and illustrations were conducted using R.3.5.3 (R Core Team 2019). Trait correlations were calculated using the *smatr* R-package (Warton et al. 2012). Principal component analysis (PCA) was performed based on four structural and three hydraulic traits using the *prcomp* function. For the PCA, the missing hydraulic trait values of *M. integrum* and *T. rotundifolia* were interpolated using the *missMDA* package. Structural equation model (SEM) analysis was used to analyze the interdependent relationships between xylem structure and hydraulics. Multiple SEMs were then computed using the *sem* function of the *lavaan* R-package (Rosseel 2012), and the best model was selected based on RMSEA and AIC values.

Results

Across the studied species, xylem K_s , SWC and P_{50} varied by 1.7-, 21.9- and 5.4-fold, respectively. Xylem embolism resistance ranged from -1.10 MPa (*Sinosideroxylon pedunculatum*) to -6.99 MPa (*Boniadendron minus*) (Figure S1 available as Supplementary data at *Tree Physiology* Online).

Structural and hydraulic trait differences between evergreen and deciduous species

In the multivariate space of PCA, deciduous and evergreen species were distinguished into two groups (Figure 2). *T*-test comparison of principal component scores between the two groups (*P*-value of PC1: 0.056, PC2: 0.031) showed that deciduous species were dominant in the upper left region of the PCA, which was characterized by high VAP and SWC but low WD. Comparative tests showed that deciduous species differed from evergreen species only in Dh , SWC and WD, with deciduous species showing higher Dh than that of evergreen ones

Table 1. Description of the 22 studied species by leaf habit.

Micromelum integerrimum, for which we only found three individuals and collected data from one for conservation purposes. Thus, hydraulic traits and growth information were missing for this species. Additionally, the secretion of viscous latex prevented accurate measurements of the hydraulic traits of *Triadica rotundifolia*. Maximum vessel length (MVL) was measured using the air injection method (Greenidge 1952), and the results are shown in Table 1. Branches at least twice as long as MVL were cut from the canopy with a 15 m extendable pruner, except for *P. tatarinowii* and *Cyclobalanopsis glauca*, from which branches longer than MVL were collected. The basal end of the branch was wrapped in a wet paper towel and tightly banded with a wrap film to prevent dehydration. The branches were double wrapped in black plastic bags and light-colored gunny bags from outside to prevent transpiration, overheating and mechanical damage during transportation to the laboratory, which was accomplished within 1 h.

The bench-top drying method was used to induce embolism in the branches, and a flowmeter (Bronkhorst 5 g/h, Ruurlo, The Netherlands) was used to measure the flow. Upon arrival at the improvised laboratory, several leaves were wrapped in aluminum zip-lock bags to equilibrate their water potential with that of the stem. They were used to monitor and measure the xylem water potential. One bagged leaf was excised, and its water potential was measured using a pressure chamber (PMS 1505 D-EXP, Corvallis, OR, USA). The measured water potential was

double-checked against that of another leaf to ensure homogeneity within the branch. Leafless branch segments were selected, ensuring that they remained longer than MVL after successive trimming. Furthermore, the segments were trimmed by ~2 cm from both ends underwater, and were immersed for at least 30 min to release xylem tension. Tension release was repeated at least twice. The segments were trimmed again at both ends. Subsequently, the basal end was shaved using a sharp cutter blade, connected directly to the flowmeter with a head pressure of ~3 kPa (Espino and Schenk 2011) corresponding to a water denivelation of 30 cm, and the native flow rate (F_0) was recorded when the flow rate measurement stabilized. Native embolism was flushed using a degassed 10-mM KCl aqueous solution at 150–250 kPa for at least 30 min. Then, the maximum flow rate (F_{max}) was measured using the flowmeter. Native and maximum K_s (K_0 and K_{max} , respectively) were calculated using the following equation (Melcher et al. 2012):

$$K = \frac{F \cdot L}{\Delta P \cdot A_w} \quad (4)$$

where F is the measured flow, L is the length of the segment, ΔP is the hydrostatic pressure difference between the sample and the water level in the reservoir and A_w is the sapwood area at the middle of the segment. A_w was assumed as the area of

Figure 3. Relationships between xylem anatomical traits and hydraulic traits, vessel hydraulically weighted mean diameter (D_h), VAP, SWC and K_s . The structural equation model (b) evidences the complexity of the relationships. Each path of the SEM model was separately represented by a reduced major axis correlation and shown in panels (a–f). Points drawn in gray (*C. glauca* and *T. rotundifolia*) on the (c) panel are outliers. From panels (d–f), *M. integririmum* and *T. rotundifolia* have xylem structural trait values but no K_s data. Each point represents the species average, and error bars are the standard errors. *: $0.05 > P > 0.01$, **: $0.01 > P > 0.001$.

within a range for which high vessel density can compensate. In addition, the thick vessel walls of the deciduous species may have compensated for the potential vulnerability of their wide vessels. The resulting similarity in terms of xylem K_s and embolism resistance between the two groups of species suggests that xylem structure converged toward the adaptation of karst species to water deficit and nutrient availability limitations, thereby explaining the coexistence of both groups.

Xylem water storage and anatomy are associated with K_s but not with embolism resistance

Our regression analysis revealed intercorrelations between VAP, D_h , SWC and K_s , such that paratracheal parenchyma, large vessels and high capacity for water storage ensured a high-water transport rate through the xylem in karst tree species. This

result is consistent with theories and functional relationships reported by various studies on species from different environments (Tyree and Zimmermann 2002, Morris et al. 2018, Janssen et al. 2020, Áritsara et al. 2021). For instance, the relationship between K_s and D_h is theoretically linked to the Hagen–Poiseuille equation wherein xylem K_s is proportional to the fourth power of the xylem vessel diameter (Tyree and Zimmermann 2002). In turn, the xylem parenchyma–paratracheal arrangement, that is, high VAP is associated with large vessels (Morris et al. 2018) and high K_s (Áritsara et al. 2021). In addition, species with high SWC have been frequently reported to show high capacitance (Ziemińska et al. 2020), which helps to maintain the integrity of large vessels having high K_s (Meinzer et al. 2003). Large-diameter vessels can transport water faster but are often vulnerable to hydraulic dysfunction (Sperry et al. 2006). To prevent vessel dysfunction, plants

Figure 4. Contributions of xylem K_s and embolism resistance (P_{50}) to the average DGR at species level within two diameter ranges. *Micromelum integerrimum* and *T. rotundifolia* have no data on K_s and P_{50} . Thus, 20 species were shown in panels (a–d); in panels (e–f), only 12 species had individuals exceeding 15 cm DBH. Each point represents the species average; error bars are the standard errors. *: $0.05 > P > 0.01$, 'ns': $P > 0.1$.

can mobilize stored water to buffer the xylem water potential and delay embolism initiation (Scholz et al. 2007, McCulloh et al. 2019). However, this buffering mechanism also depends on the xylem parenchyma structure (Vesala 2003, Ziemińska et al. 2020). Specifically, xylem parenchyma cells channel water from storage tissues to vessels (Zwieniecki and Holbrook 2009, Brodersen et al. 2010), and relatively strong connectivity between xylem parenchyma and vessels facilitates this exchange (James et al. 2003, Zwieniecki and Holbrook 2009). In karst habitats, when soil water supply decreases, storage water in plants may either (i) temporarily supplement the transpiration stream, thereby maintaining photosynthesis and producing additional biomass, or (ii) maintain the vessels in a functional state, such that they can be readily operational as soon as soil water becomes available again. The second

mechanism seems most likely because transpiration can be rapidly halted when fine roots sense a water deficit (Carminati et al. 2020, Rodríguez-Domínguez and Brodribb 2020). The independence of P_{50} to the studied anatomical traits can be associated with the strong correlation between P_{50} and inter-vessel pit structure (Levionnois et al. 2021), but the structural compensation discussed above warrants further investigation of such a relationship among karst species. Therefore, vessel dimension, parenchyma arrangement and water storage of karst tree species support xylem hydraulic efficiency.

Xylem hydraulic efficiency and safety promoted tree diameter growth in karst habitats

We observed that the tree species that achieved relatively high K_s grew faster than those with lower K_s . This finding

Figure 5. Contribution of embolism resistance (P_{50}) to growth acceleration (r_2) with increasing tree size based on the growth model proposed by Iida et al. (2014). Only nine of the 22 species had significant size–growth scaling relationships, the correlation for all species is in supporting information Figure S2 available as Supplementary data at *Tree Physiology Online*. Data show the species average, and the error bars of P_{50} are the range between the 0.025 and 0.975 quantiles from the bootstraps of the vulnerability curve. No error bar was computed for r_2 and stdGR_{15} . **: $0.01 > P > 0.001$.

is consistent with the positive correlation observed previously between theoretical xylem conductivity and growth rate in tropical seasonal rainforests (Fari et al. 2012). Species with high hydraulic efficiency can transport large amounts of water within a short period. The ephemeral water availability after rainfall in karst habitat (Fu et al. 2016) may explain why trees with high hydraulic efficiency grow faster than trees with low efficiency. Overall, the positive correlation between K_s and DGR was stronger than that between absolute P_{50} and DGR, and the latter correlation became positive and significant in trees with DBH above 15 cm. These two correlations suggest that species with relatively high hydraulic conductance and high embolism resistance grew faster. The results also indicated that the correlations between hydraulic traits and tree growth were stronger than the correlations between anatomical traits and growth of karst tree species. This is consistent with the findings in a seasonal tropical forests where traits directly associated with water transport and photosynthesis had stronger correlation with tree growth than more commonly measured traits (Rowland et al. 2021).

In terms of safety, the observed positive correlation between absolute P_{50} and tree growth in large trees contradicts tradeoffs or non-significant relationships reported by other studies (Hajek et al. 2014, Ahmad et al. 2018, Eller et al. 2018, Rowland et al. 2021). The importance of embolism resistance for tree growth in karst habitat can be an adaptation to the shallow root layer leading to intermittent water availability (Fu et al. 2016). Indeed, a water and biomass model on seasonal dry tropical forests showed that some trees lost their leaves quickly after intermittent rainfall (Xu et al. 2016), probably due to low hydraulic safety, thus, limiting tree growth. The positive correlation between absolute P_{50} and tree growth in large trees,

emphasized by that between absolute P_{50} and standardized growth rate at 15 cm DBH, coincides with the exposure of large trees to the high-water tension at the canopy level (Hartlyn 1992). Thus, the need for fast and safe water transport at the canopy overrides the effect of light and carbon assimilation on the growth of trees growing under water-deficit conditions (Muller-Landau et al. 2006, Rowland et al. 2021).

Within the last decade, several researchers have integrated plant hydraulic traits into biosphere models and predicted with more or less accuracy water and carbon budget at plant, ecosystem and regional scales (Christoffersen et al. 2016, Xu et al. 2016, Mencuccini et al. 2019). The empirical correlation of hydraulic efficiency and safety with tree growth observed in this study will allow us to select and calibrate models that better fit karst environments. Nevertheless, tree growth is a complex mechanism, and realistic models should not disregard whole-plant trait coordination, macro- and microclimate, and biotic interactions between cohabiting organisms. Overall, our results illustrate the importance of fast and safe water transport for tree growth on karst formations, which may explain the lack of tradeoff between hydraulic efficiency and safety.

Greater cavitation resistance is correlated with higher growth acceleration with increasing DBH

Absolute P_{50} was strongly and positively correlated with the slope r_2 , i.e. growth acceleration, based on the growth–size relationship model of Iida et al. (2014). Two mechanisms are proposed to explain the relationship between P_{50} and tree growth acceleration. (i) Iida et al. (2014) partly attributed the decreasing growth rate with increasing stem diameter with the accumulation of dead wood. Reciprocally, physiological traits that extend sapwood lifespan may reverse this trend. Indeed, sapwood with high embolism resistance could have a longer lifespan as emboli shorten the vessel lifespan (Jacobsen et al. 2018). Thus, the resulting increase in functional sapwood area may be consistent with the increasing growth rate with increasing stem diameter. (ii) Species with high embolism resistance are compromised by slower growth at an early age; as trees of these species grow taller, they acquire greater access to light and water (deeper rooting) resources, which in turn facilitate faster growth (Meinzer et al. 2011, Gleason et al. 2018). The correlation between more negative P_{50} and high growth acceleration potentially integrate mechanism such as xylem lifespan, resource acquisition and forest succession. Our results highlighted that embolism resistance modulates tree growth dynamics in karst habitats, but clarifying the related physiological mechanisms requires further investigations.

Conclusion

Our results demonstrated structured relationships linking xylem anatomy, hydraulics and tree growth rate and dynamics in a

karst habitat. The xylem structure alone is hardly related to tree growth unless the hydraulic efficiency and safety determined by this structure are considered. For instance, large vessels, high-water storage and paratracheal xylem parenchyma promoted hydraulic efficiency. Moreover, there was no significant tradeoff between hydraulic efficiency and safety, and both promoted tree diameter growth. In addition, stronger xylem embolism resistance was linked to higher growth acceleration with increasing tree size. Furthermore, our results highlight that, in addition to hydraulic efficiency, hydraulic safety significantly influences the growth of karst trees, particularly that of large trees. The close association between water regime and tree growth rate and dynamics in karst forests demonstrates a high sensitivity of karst habitats to climatic disorders, influencing forest production and mortality, and consequently, the carbon sequestration efficiency of the ecosystem. Therefore, we strongly recommend the direct integration of empirically measured hydraulic traits into models aiming to analyze actual and future primary production and carbon stock distribution, particularly in regions with abundant karst ecosystems.

Acknowledgments

We express our sincere gratitude to the managers of the Mulu Protected Area for allowing us to perform the study on-site, and to the students from the Plant Ecophysiology and Evolution group for their contribution to the measurement of annual growth. We are thankful to the Editor and the anonymous reviewers for their contribution to the improvement of the manuscript.

Figure 2. Principal component analysis synthesizing the relationships between xylem anatomy and hydraulic across 22 karst species. Each point represents the species average. Deciduous and evergreen species are shown in open and filled points, respectively. *Dh*: vessel hydraulically weighted mean diameter, *SWC*: xylem saturated water content, *WD*: sapwood density, *K_s*: sapwood specific hydraulic conductivity, *P₅₀*: xylem water potential at 50% loss conductivity, *APF*: axial parenchyma fraction.

(Table S1 available as Supplementary data at *Tree Physiology Online*).

Relationships between xylem structure, hydraulic function and tree growth rate

No significant tradeoff has been observed between *K_s*, *SWC* and *P₅₀* (Figure S2 available as Supplementary data at *Tree Physiology Online*). Among all studied structural traits, *Dh*, *VAP*, *VFc* and *WD* showed the strongest correlations with *K_s* and *SWC*, but none of the studied anatomical features was significantly correlated with *P₅₀* (Figure 2). Because *VAP* and *VFc* exhibited a strong negative correlation due to spatial complementarity ($R^2 = 0.52$, $P < 0.001$), only one of the two, that is, *VAP*, was integrated into the analysis of xylem structure–hydraulic relationships. Furthermore, regression analysis showed significant positive correlations between *Dh*, *VAP*, *SWC* and *K_s* (Figure 3), suggesting strong interactions between vessel dimensions, parenchyma structure, water storage and *K_s*. Based on SEM, the direct path coefficient between *VAP* and *K_s* was weaker than indirect paths via the contributions of *VAP* to *Dh* and *SWC*, and then to *K_s*. *P₅₀* was excluded from SEM due to the lack of correlation with the other traits (Figure 3g).

None of the traits that significantly distinguished evergreen from deciduous species directly correlated with diameter growth rate (*DGR*) (Table S1 and Figure S2 available as Supplementary data at *Tree Physiology Online*). Regardless of the tree diameter classes, average *DGR* was positively correlated with *K_s* but not with *SWC* or *P₅₀* (Figure 4a and b, Figure S2 available as Supplementary data at *Tree Physiology Online*). Among trees with *DBH* ranging from 5 to 15 cm, *K_s* and *P₅₀* were not significantly correlated with *DGR* (Figure 4 c and d). Furthermore, among

trees with *DBH* exceeding 15 cm, both *K_s* and absolute *P₅₀* were positively correlated with *DGR* (Figure 4e and f).

Relationships between hydraulic functions and tree growth dynamics

Based on the growth–size relationship model of Iida et al. (2014), only 8 of the 22 species showed a significant size-dependent growth rate (Table S2 available as Supplementary data at *Tree Physiology Online*). Slope factor, r_{21} , was strongly and positively correlated with absolute *P₅₀* across the species with significant size-dependent growth (Figure 5). The relationship remained significant when the other species were added to the analysis (Figure S3a available as Supplementary data at *Tree Physiology Online*). Additionally, the absolute value of *P₅₀* was positively correlated with the tree growth standardized for 15 cm *DBH* trees (Figure S3b available as Supplementary data at *Tree Physiology Online*).

Discussion

Our results revealed that xylem hydraulic efficiency increased with xylem vessel diameter, paratracheal parenchyma arrangement and water storage in subtropical karst tree species. Furthermore, xylem hydraulic efficiency and embolism resistance promoted fast tree growth in large trees. Moreover, xylem embolism resistance was related to increasing growth acceleration as tree diameter increased.

Difference in structure and similarity in hydraulic traits between evergreen and deciduous tree species

Our comparative analyses showed that the branch xylem of evergreen and deciduous tree species significantly differed in *WD* and vessel diameter (Figure 2, Table S1 available as Supplementary data at *Tree Physiology Online*). The significantly low *WD* of deciduous species, compared with evergreen species, was consistent with previous reports (Méndez-Alonzo et al. 2012, Zhao et al. 2016). Evergreen species tended to compensate for their narrower vessels with marginally higher vessel density to achieve a hydraulic efficiency similar to that of deciduous species (Table S1 available as Supplementary data at *Tree Physiology Online*). It is important to emphasize that this kind of compensation may not suffice in non-karst habitats because it has been shown that deciduous species have significantly higher *K_s* values than evergreen species in savanna and tropical seasonal dry forests (Choat et al. 2005, S.-B. Zhang et al., 2022). In fact, vessel packing limitation rule governs a one-power tradeoff between vessel diameter and density (Zanne et al. 2010, Rita et al. 2020), and vessel diameter has four-power effects on hydraulic efficiency (Tyree and Zimmermann 2002). Nevertheless, in karst habitats, the need for hydraulic safety may entail limited vessel expansion in deciduous species. Thus, vessel diameter was maintained
